# EXPERIMENTAL STUDY ON MICROSERVICES ORCHESTRATION WITH AMAZON STEP FUNCTION

## **Background**

- Cloud computing has become an immensely growing market in 2022.
- Amazon Web services (AWS) is dominating the cloud market by almost 34%

- AWS Step Functions is a serverless orchestration service that lets you integrate with AWS Lambda functions and other AWS services to build business-critical applications.
- Through Step Functions' graphical console, you see your application's workflow as a series of event-driven steps.

### **Problem Overview**

- Not enough Research have been done for AWS Step Function in terms of Performance and Cost.
- What is the advantange of Step Function when comparing with Event-Driven AWS application and Code-based application?

**Event-Driven Application** 

Code-Based **Application**

# EXPERIMENTAL STUDY ON MICROSERVICES ORCHESTRATION WITH AMAZON STEP FUNCTION

### **Experiments & Results**

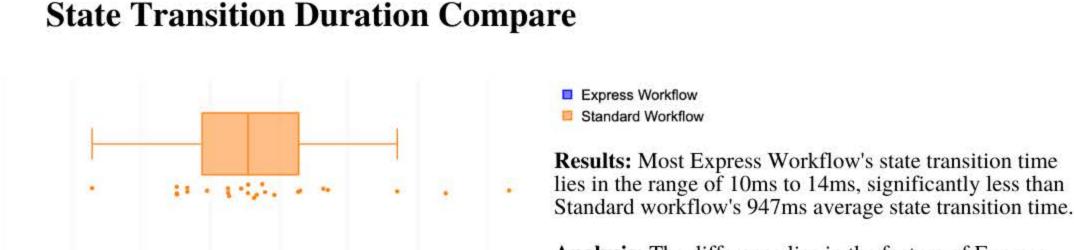

### **Experiments Between Step Function Express and Standard**

Express Workflow

Standard Workflow **Results:** Average execution time of Express workflow is 3.199s, 37% faster than Standard

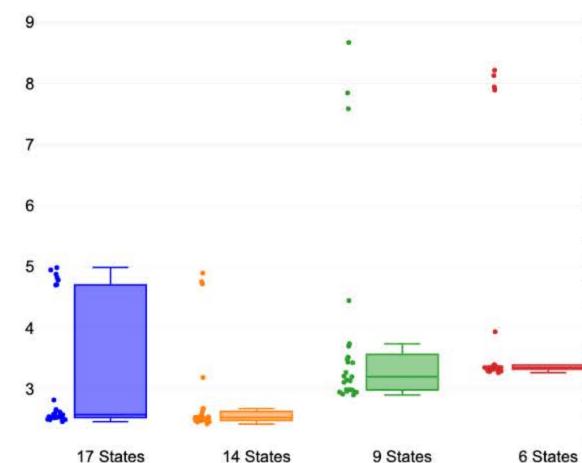

Analysis: JSON file as event call to simulate order, short-live execution, idempotent action e.g. DynamoDB put operation. All above features of application align with Express workflow more closely

Standard Workflow Results: Most Express Workflow's state transition time lies in the range of 10ms to 14ms, significantly less than

**Analysis:** The difference lies in the feature of Express workflow that it doesn't store state transition information, which greatly saves the transition time between states

#### Number of States Graph for Express Workflow

**Observation 1:** The average running time of the 17-States workflow is 3.1996s, slightly slower than the 14-States workflow's 2.82488s.

Analysis 1: Express workflow doesn't store state transition information therefore adjusting the number of Choice states only contributes to limited performance improvement

**Observation 2:** The average running time of the 9-States & 6-States workflow is 3.8224s and 4.11444s respectively, longer than 17-States & 14-States workflow.

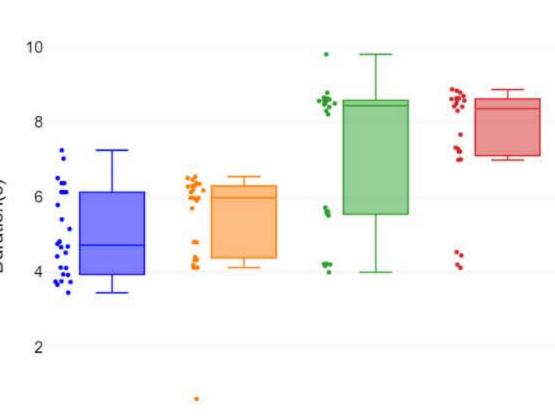

Analysis 2: Workflow with fewer states should perform better since the State Transition Time is saved. This abnormality demonstrates that Step Function orchestrates services more efficiently than Lambda orchestration

Observation 3: All four workflow's data layout displays group pattern: lie in two groups

Analysis 3: The pattern where data points from all four workflows lie in two major ranges is caused by the effect of the Lambda function's warm/cold start on ASF execution time

#### **Number of States Graph for Standard Workflow**

State Transition Duration(ms)

17 States

**Observation 1:** The average running time of the 17-States workflow is 5.061s, similar to the 14-states' 5.3887s.

Analysis 1: State transition of the choice states has a very limited effect on performance.

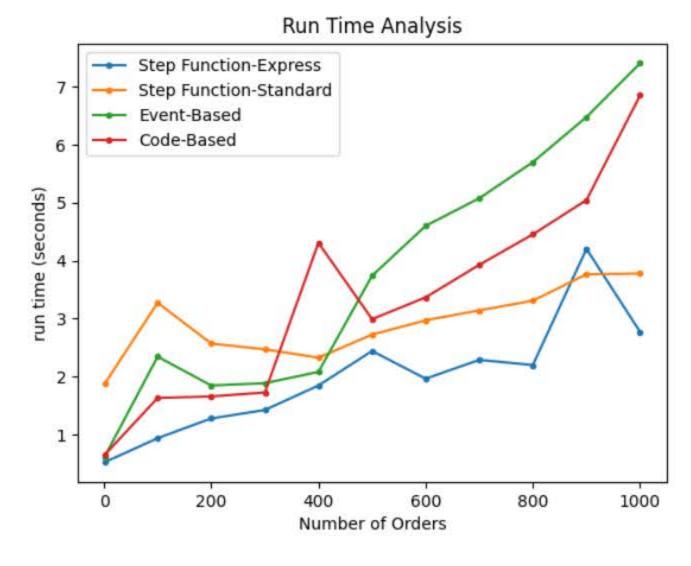

**Observation 2**: From 14 states to 9 states, the average running time increased to 7.32609s.

Analysis 2: Step Function orchestrates services more efficiently compared with invoking other AWS services within the Lambda function.

**Observation 3**: Data points grouping layout doesn't show a specific pattern.

Analysis 3: Lambda cold/warm start doesn't have a significant influence on the Standard Workflow's performance.

#### 14 States Experiments Between Step Function, Event-Based, Code-Based

1 to 100

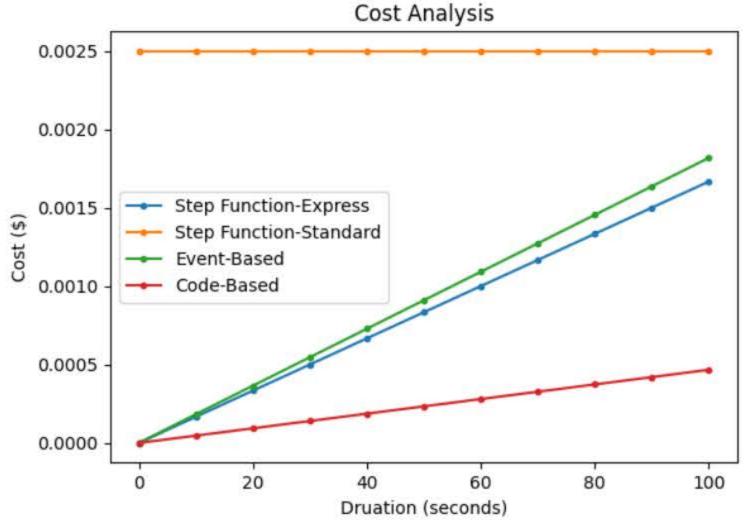

All four applications showed the big jump.

200 to 400

All four application starts to decrease.

400 and 500

Event-based application starts to increase dramatically, Two step function grow steadily.

AWS step function standard \$0.0025 / 100 states

AWS step function express \$0.0000166667 per second

lambda(\$0.0000166667 / s)

SNS(\$0.5 / million notification)

DynamoDB(\$1.5 per million read and write pair)

#### Conclusion

#### In the experiments between Express and Standard workflow

- Adjusting the number of Choice states only contributes to subtle improvement in performance for Express workflow
- Standard workflow's feature of storing state transition information prolongs state transition time between states
- Service orchestration with Step Function performs better than invoking AWS services within the Lambda function
- Express ASF's performance is significantly influenced by the Lambda function' code/warm start. While this factor doesn't impact Standard Workflow too much.
- Express workflow's feature of not storing state transition information saves state transition time between states
- Short-term, event-based application with idempotent operation is more suitable to implement with Express workflow.
- In Standard workflow, reducing the nonservice state only has little influence on the performance efficiency

#### **Future Steps**

- No available backend API to directly export execution logs, further research could add tools to enable automatic export execution logs.
- The current application is more aligned with Express workflow's feature, further research could be executed on applications that fit Standard workflow more closely, to test its performance and cost
- One limitation is that the current application is relatively simple, contains only limited AWS resources, future steps could add more components to simulate real-world applications
